## **Model Optimization and Tuning Phase**

The Model Optimization and Tuning Phase involves improving our machine learning recommendation model to get the best performance. This includes adjusting the model's parameters, experimenting with different algorithms, and selecting the most suitable model based on evaluation metrics such as accuracy, precision, recall, and RMSE (Root Mean Squared Error).

Our restaurant recommendation system was designed to suggest similar restaurants based on location, user ratings, cuisines, and cost using collaborative filtering and content-based filtering techniques.

Model		

Model 1:	Tuned Hyperparameters
Content-Based	
Filtering	<ul> <li>Similarity Metric: Cosine similarity was used as the primary metric to compute similarity between restaurants based on features like cuisines, rating, and cost.</li> <li>Top N Recommendations: The number of top similar restaurants returned was tested with values like 5, 10, and 15.</li> </ul>

**Hyperparameter Tuning Documentation (8 Marks):** 

```
del recommend(name, cosine_similarities = cosine_similarities):

# Create a list to put top restaurants
recommend_restaurant = []

# Find the index of the hotel entered
idx = indices[indices = name_index[0]]

# Find the index of the hotel entered
idx = indices[indices = name_index[0]]

# Find the index of the hotel entered
idx = indices[indices = name_index[0]]

# Extract top 30 restaurant indexes with a similar cosine-sim value and order them from bigges number
score_series = pd.Series(cosine_similarities[idx]).sort_values(ascending=False)

# Extract top 30 restaurant indexes with a similar cosine-sim value
top30_indexes = list(score_series.iloe[0:31].index)

# Names of the top 30 restaurants
for each in top30_indexes:
recommend_restaurant append(list(df_percent.index)[each])

# Creating the new data set to show similar restaurants

# Creating the new data set to show similar restaurants

# Create the top 30 similar restaurants with some of their columns

# Create the top 30 similar restaurants with some of their columns

# Create the top 30 similar restaurants with some of their columns

# Create the top 30 similar restaurants with some of their columns

# Create the top 4 new appending DataFrame(df_percent[[cuisines', Mean Rating, 'cost']]|df_percent.index = each].sample()))

# Drop the same named restaurants and sort only the top 10 by the highest rating

# frow = df_new.drop_duplicates(unbext=['cuisines', Mean Rating', 'cost'], keep=False)

# Drop the same named restaurants and sort only the top 10 by the highest rating

# frow = df_new.drop_duplicates(unbext=['cuisines', Mean Rating', 'cost'], keep=False)

# print(TTOP %s RESTAURANTS LIKE %s WITH SIMILAR REVIEWS: '% (str(len(df_new)), name))

# freturn df_new
```

## 

## **Final Model Selection Justification (2 Marks):**

Final Model	

Model 1: Content-	Reasoning
Based Filtering	
	Selected due to its simplicity and good performance without requiring detailed user history. It gave interpretable and relevant results using restaurant features like cuisines, ratings, and cost.
